

An agent does the whole vendor onboarding and contract file, and is **structurally unable to sign it or pay it**. Your team keeps the decision, and for the first time gets an auditable record of what was actually checked.

\$3.05B lost to business email compromise in 2025 FBI IC3, #2 crime type by loss	74% of organisations hit by BEC last year AFP Payments Fraud Survey	\$123,005 median loss per incident 24,768 reported cases	57% of chased funds the FBI recovers — and only within hours Recovery Asset Team, 2025
---	--	---	---

WHAT BREAKS TODAY

An invoice arrives from a domain one character off the real one, saying the bank account changed. The control that should stop it is a person in accounts payable looking at a PDF for four minutes. Nobody compares the sender domain to the vendor's real one, the change of bank details travels by the same email channel already compromised, and no record survives of what was checked.

WHAT COUNTERSIGN DOES

- 1

Reads the document, deterministically
Every field keeps the page and the box it came from. A value it cannot anchor is returned absent, never invented. Account numbers are masked before any model sees them.
- 2

Verifies the counterparty against live data
Is this the same legal entity, or a namesake? Is the coverage adverse? Is the invoiced address a business or a mail drop?
- 3

Sweeps the domain space
Forty confusable variants across eight attack classes, checked against the live registry. Which are already registered, and is the sender one of them?
- 4

Hands a person one decision
A verdict where every claim links to the source it rests on, and a signature envelope prepared and waiting.

WHY THIS IS NOT ANOTHER AI TOOL

The agent asks to sign. Every run. It is refused. Every run.

Signing and releasing payment are not powers withheld by an instruction the model could talk its way around. They are capabilities no agent in the system holds, checked in code, and the refusal is written to an append-only log rather than hidden.

```
seq=5  envelope-preparer
      foxit_execute_signature  DENY
```

A tool that is not declared resolves to no capability and is denied by default. The build fails if anyone ever grants an agent the power to sign.

MEASURED, NOT ASSERTED

Verdict accuracy on labelled invoices	6 / 6
Same invoice, same verdict, every time	6 / 6
Claims carrying a verifiable source	100%
Fabricated citation rejected	yes
Signature requested and refused	12 / 12
Time per assessment	39s
Cost per assessment	~\$0.15

Against four minutes of a person's time, at roughly \$22.50 per verification event.

Where it sits Between the invoice arriving and the payment run. No change to your ERP: documents in, a dossier and a prepared envelope out. Deploys to your own cloud; your documents never train anything.	What it costs to be wrong once \$123,005 at the median, of which the FBI recovers just over half, and only if someone notices the same day. The check costs fifteen cents.
